**Plain Language Summary:** In this paper, we propose an H-infinity filtering approach for the prediction of bias in post-processing of past predictions and past measurements regarding weather forecast. The proposed H-infinity filtering adopts minimax strategy. The proposed H-infinity filtering approach minimizes maximum possible errors whereas a recently proposed approach that adopts the Kalman filtering (KF) minimizes the mean square errors.

- The proposed approach outperforms the method based on the KF with less complexity and no prior noise information.
- This approach can be applied for prediction of any meteorological parameters as long as NWP is employed.

---

Figure 1. Block diagram of post-processing by a filter such as the Kalman filter or H-infinity filter. An numerical weather prediction (NWP) output of $m_{K+1,f}$ is corrected by $y_K$, and updated as $m'_{K+1,f}$ based on past observation, i.e. weather measurement.
